

Cloud formation

- Cloud formation is a service that allows you to define and provision AWS infrastructure using code, in a safe, repeatable, and automated manner. It helps in managing and provisioning resources like servers, databases, networking components, etc.
- cloudformation allows you to define your cloud resources using JSON or YAML templates, which can be version-controlled, shared, and reused. These templates describe the desired state of your cloud infrastructure.

stack:

- In cloudformation, a **stack** is a collection of AWS resources that you can manage as a single unit.
- When you create a stack, you specify the resources you want to create and manage by providing a **CloudFormation template**.
- This template defines the desired infrastructure, and CloudFormation provisions the resources for you according to the template.

Drift detection

Drift detection in AWS CloudFormation is a feature that helps identify any unexpected changes (drift) between the resources in your stack and the definitions in your CloudFormation template. This can occur if a resource has been modified outside of CloudFormation, such as manually in the AWS Management Console or via the CLI(now deleted my ec2 instance its showing drifted)

[CloudFormation](#) > [Stacks](#) > [stack-1](#) > Drifts

Drifts

Detect stack drift

Stack drift status

Drift detection enables you to detect whether a stack's actual configuration differs, or has drifted, from its template configuration. [Learn more](#)
